

# Non-reproducibility is an integral part of a productive and efficient scientific enterprise

- A key task for biomedical research is to scan a large number of hypotheses
- Efficient scanning of a large number of candidates requires fast and frugal methodologies, like use of small sample sizes and surrogate endpoints.
- By their very nature, however, fast and frugal methods are prone to producing false positive signals of activity.
- Drugs that look promising in preclinical studies but fail conceptual reproduction in phase 2 trials are to some degree a byproduct of rational decision-making across a sequence of investigations rather than poor study design.
- Failed conceptual reproduction maps the boundaries of a theory.
- Observation of phenomena in one experimental system, but not in another, often leads to deeper understandings of processes and of experimental systems. It defines the boundaries of a theory's explanatory power.

Overall median power of 730 primary neuroscience studies: 21 %

# Falsch Positive und Inflation der Effektgrösse

- 'Winner's curse', Regression to the mean

"Publication bias is highly prevalent (present in the literature describing the efficacy of at least 16 of 18 interventions) and accounts for around 30% of the reported efficacy of candidate neuroprotective interventions."

**Publication bias in reports of animal stroke studies leads to major overstatement of efficacy**

Emily S Sena, H. Bart van der Worp, Philip M.W. Bath, David W Howells and Malcolm R Macleod (PLoS Biol. 2010 Mar 30;8(3):e1000344)

## Perspective

# Distinguishing between Exploratory and Confirmatory Preclinical Research Will Improve Translation

**Jonathan Kimmelman<sup>1\*</sup>, Jeffrey S. Mogil<sup>2</sup>, Ulrich Dirnagl<sup>3,4,5</sup>**

# Exploratory vs confirmatory research

In **exploratory investigation**, researchers should aim at generating robust pathophysiological theories of disease.

In **confirmatory investigation**, researchers should aim at demonstrating strong and reproducible treatment effects in relevant animal models.

Protocols and publications should pre-specify whether they are “exploratory” or “confirmatory” studies, with the latter category reserved for studies that aim at demonstrating promise of clinical utility for an intervention.

# Exploratory vs confirmatory research

	Exploratory 'Discovery'	Confirmatory
<b>Hypothesis</b>	(+)	+++
<b>Establish pathophysiology</b>	+++	(+)
<b>Sequence and details of experiments established at onset</b>	(+)	+++
<b>Primary endpoint</b>	-	++
<b>Sample size calculation</b>	(+)	+++
<b>Blinding</b>	+++	+++
<b>Randomization</b>	+++	+++
<b>External validity (aging, comorbidities, etc.)</b>	-	++
<b>In/Exclusion criteria</b>	++	+++
<b>Test statistics</b>	+	+++
<b>Preregistration</b>	(-)	++
<b>Find what might work: Sensitivity (accept Type I errors)</b>	+++	+
<b>Weed out false positives: Specificity (accept Type II errors)</b>	+	+++

# Ursachen für Nichtreplizierbarkeit

- Fraud
- False positive (Replication = true Null result)
- Methodical (Incompetence, biased study design, low power, etc.)
- Poor reporting (incl. 'tacit knowledge')
- Random variation

# Replicating a statistically significant finding

$$p = 0.049 \quad (p < \alpha = 0.05)$$

Assume that the experimental result is correct, i.e. measured difference equals (unknown) treatment effect.

Repeat experiment under identical conditions.

*What is the probability to replicate the significant findings?*

**50 %!**
